The availability of structures with nearly ideal, well-controlled properties has made semiconductor heterostructures a testing ground for solid-state physics. These structures have had a profound impact on basic research in semiconductor physics by opening new possibilities for studying low-dimensional electrons, as well as the atomic and electronic properties of interfaces.

In contrast to conventional tight-binding methods in which overlap integrals between atomic orbitals are neglected, the present EHNTB method used for electronic state calculations explicitly calculates all distant-neighbor overlap and energy integrals between atomic orbitals in a QB up to the sixth-nearest neighbor and enables one to calculate the oscillator strength for dipole-allowed transitions directly from a linear combination of momentum matrix elements between atomic orbitals ...

Often, during electronic transitions, the initial state may have the electron in a level that is excited for both vibration and rotation. In other words,  $n=0$ ,  $v$  does not = 0 and  $r$  does not = 0. This can be true for the ground state and the excited state. In addition, due to the Frank Condon Factor, which describes the overlap between vibrational ...

Spectroscopy is the study of the interaction between matter and electromagnetic radiation as a function of the wavelength or frequency of the radiation. Historically, spectroscopy originated as the study of the wavelength dependence of the absorption by gas phase matter of visible light dispersed by a prism. Matter waves and acoustic waves can also be considered forms of radiative energy, and ...

Ni is envisaged as a divalent ion which plays little role in the electronic bonding and its 3d levels are localized, lying near the top both of the valence states. This model accounts well for both the valence band XPS data and the low energy optical transitions.
